and the.txt file is created as the filename with a space and then the contents are stored inside. I then went through the.txt file in notepad and there are spaces at the beginning of each line and when I try to join them together using a character that has a space as a delimiter I get the following error: Warning! Line 1312, in raise ValueError("Line %s, char %s can't be joined by %s" % (n, i, s)) ValueError: Line 1312, char 0 can't be joined by [B-node {298, 99} B-9-node {308, 100}] My question is: how can I ignore the white spaces that exist at the start of the lines in the.txt file and how can I join the lines together that are correctly separated by white spaces? A: File.readlines() will do exactly what you need. Note: File.readlines returns a list of lines. Each line is a string. A line is represented by the characters of the string, including line terminators, but not including the string itself. For Example: with open(infile) as infile: lines = infile.readlines() print(" ".join(lines)) will give you your result. If your file has newline as a line break, you can use read() instead of readlines(). Show HN: Making Money on YouTube Using a Crowdfund

Project - mcgwiz ===== mcgwiz I made this a month ago, and have been watching some of the great comments and critiques on this project. So, here is another stab at the concept: [ I will also admit that it is possible to rip off the concept of what I have done, but the spirit of what I have done is not captured in 82157476af
